The purpose of this paper was to systematically investigate the influence of acid rain environments on the seismic behaviour of a reinforced concrete (RC) column. Six RC column specimens with shear span ratios of 2.84 were tested under low cyclic reversed loads after being subjected to accelerated corrosion tests in an artificial climate.

As it is seen, most investigations have focused on ductility and energy dissipation of HSC columns, and some efforts have been made to propose novel approaches to improve its seismic behavior. Despite these investigations, a review of the literature indicates that after ACI318-14 was published, there have been rare experimental attempts to investigate the various modes of failure and damage states to capture the corresponding performance levels for the reinforced HSC columns of Special ...

This paper presents an experimental study on seismic behavior of ultra-high performance steel fiber reinforced concrete (UHPSFRC) columns. Based on a series of cyclic loading tests on 14 UHPSFRC specimens subjected to combined static axial loading and cyclic lateral loading, the investigation and analysis have been carried out on crack status, failure modes, hysteretic loops, skeleton curves, strength and stiffness degradation, energy dissipation capacity and ductility of UHPSFRC columns.

The stone blocks in the broad gable were connected by metal clamps during restoration at the beginning of the 20th century. In order to study the seismic performance of the strengthened stone masonry structures, an experimental investigation of seismic behaviour of a physical model of the Protiron was performed on the shaking table.

This paper investigates the seismic behaviour of moment-resisting timber frames with beam-column joints fastened with expanded tubes and reinforced with Densified Veneer Wood. Laboratory experiments are carried out on single joints to investigate the cyclic behaviour and, more specifically, the impairment of strength, the ductility ratio and the equivalent viscous damping ratio.

The current paper presents and discusses an experimental investigation carried out for characterizing the seismic behaviour of CFS strap-braced stud walls. The experimental campaign is principally focused to study the global response of CFS strap-braced walls designed according to an elastic approach.

In this study, the seismic behavior of corroded RC columns was experimentally studied with a focus on the comparison between two different accelerated corrosion techniques by using artificial climate environment (ACE) and electrochemical chloride extraction (ECE). To do this, six RC square columns were designed and fabricated as the test specimens.

Based on the tested hysteresis loops, the seismic behaviors of MCS wall, diagonal and cross BPCS walls are investigated and compared in terms of lateral load-displacement capacity, displacement ductility, stiffness degradation and energy dissipation in the following subsections (the numerical results are used for SW3-1.5); the influences of SSR and bracing type on the seismic behavior of the BPCS walls are also analyzed and discussed.

Five 3/4-scale reinforced concrete beam-column joints were tested to investigate the seismic behavior of the joints. The variables in the tested specimens include column orientations and the presence of slabs on the top of beams. The specimens were subjected to quasi-static load reversals to simulate earthquake loadings.

Cyclic loading tests were conducted to investigate the seismic behavior of the PC columns with proposed connections as well as the feasibility and reliability of novel box connections. The failure mode, hysteretic behavior, bearing capacity, ductility, stiffness degradation and energy dissipation were obtained and discussed.
